Dynamsoft Document Viewer

Sample document -- a real text layer

This sample exists so you can try full-text search without hunting for a suitable PDF first. Every glyph on these pages is a real text object drawn with the Helvetica font, so any PDF viewer -- and the annotation studio hosting this sample -- can extract and index every word.

Try it now: click the magnifier in the canvas toolbar (or press Ctrl+F) and search for the word annotation. You should find three matches across this document, and the viewer jumps to each one as you step through them.

You can also search for: search, text, OCR, redaction, sample.

Nothing here leaves your machine: the file is bundled with the demo, loaded locally, and parsed by the WebAssembly engine in your browser tab.

Why some PDFs cannot be searched

A PDF can store letters in two very different ways. A text layer stores each character as a character with a font reference -- that is what search reads. An outlined or scanned page stores shapes: the letters are vector curves or pixels, and no search engine can find a word in them.

If a document produces zero results in the search panel, it almost certainly has no text layer. Standard extraction tools return zero characters for such files. OCR is the only way to recover searchable text from them -- the letters must be recognized back into characters before they can be indexed.

The word annotation appears on this page too -- by design.

Tip: files exported from design tools with fonts converted to outlines, or stamped and flattened through certain pipelines, lose their text layer the same way a scan does. Rendering still looks perfect; search finds nothing.

What to try in this demo

* Search the full text (Ctrl+F) -- try annotation, search or redaction.
* Annotate with the native toolbar: shapes, ink, text boxes and stamps.
* Mark a region for redaction, then export a flattened PDF to burn it away.
* Export the pages to PNG, JPEG or a multi-page TIFF archive.

Every feature runs locally in your browser. The document never leaves your machine -- open, annotate, redact and export all happen inside this tab.

This sample reloads fresh every time you restart the demo, so it is always a clean starting point for trying the next feature.
